Mechanics of Materials

Lecture 29 - Statically Indeterminate Beams

Dr. Nicholas Smith

Wichita State University, Department of Aerospace Engineering

27 Apr, 2020

schedule

- 27 Apr - Statically Indeterminate Beams
- 29 Apr - Beam Review, Exam 3b assigned
- 1 May - Recitation, HW 10 Due
- 4 May - Stress Concentration
- 6 May - Buckling, Exam 3b Due
- 8 May - Review, HW 11 Due, Final Project Portion assigned

outline

- statically indeterminate beams
- indeterminate beams - superposition
- group problems

statically indeterminate beams

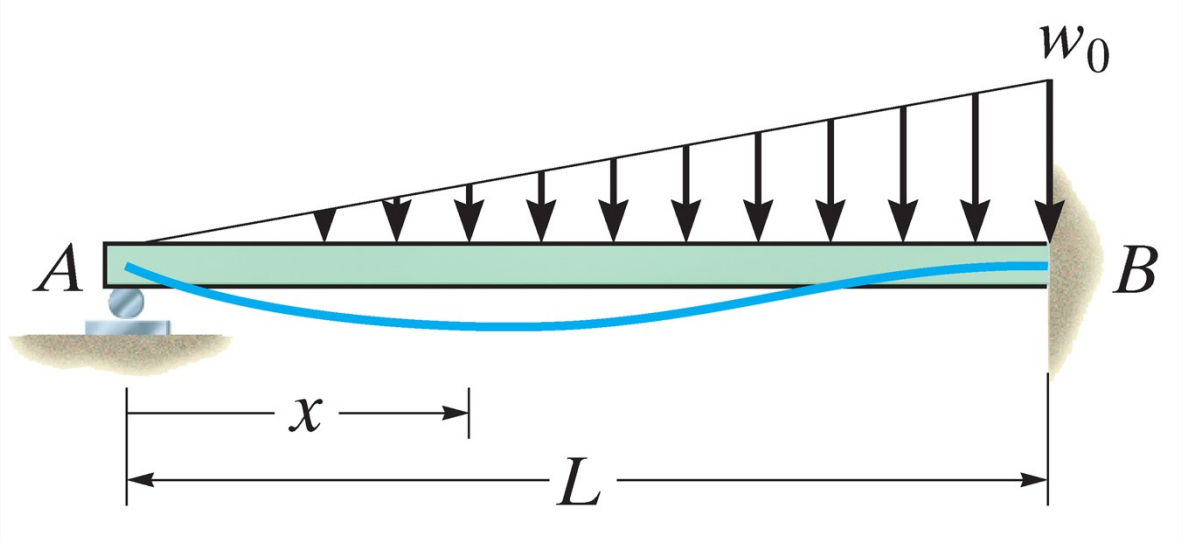
statically indeterminate

- If we have redundant supports, we can have some difficulty finding the displacement
- There are several approaches to solve these problems, we will consider direct integration and superposition

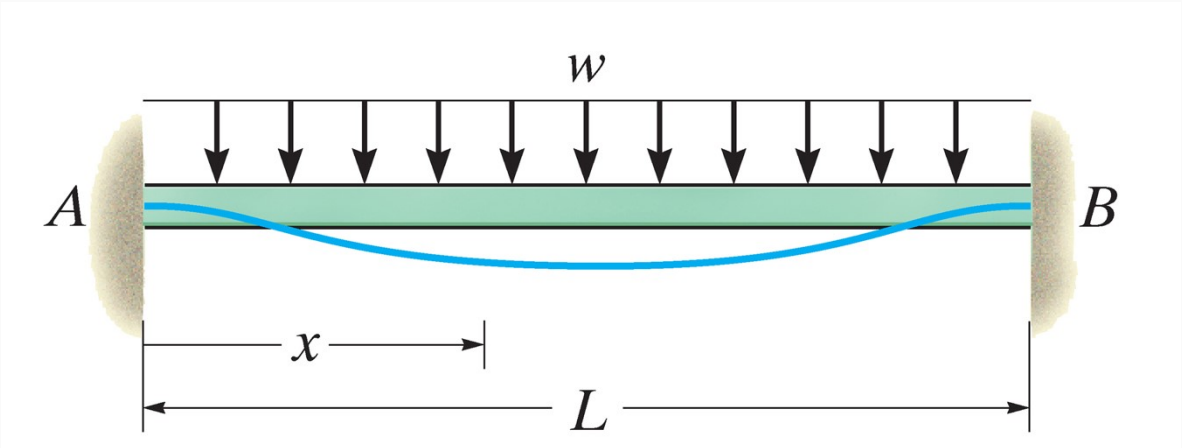
integration

- We can take the extra unknowns and include them in our formulation for $M(x)$
- They will be solved for with the extra boundary conditions applied

example 12.17



example 12.18

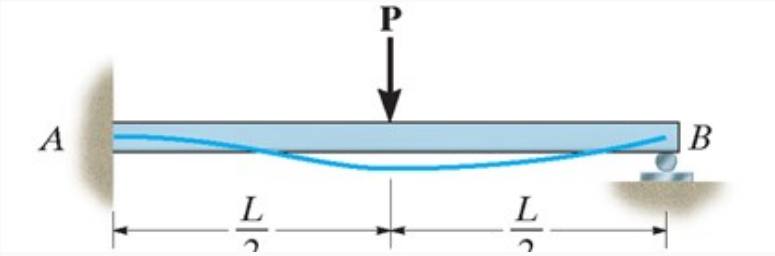


indeterminate beams - superposition

superposition

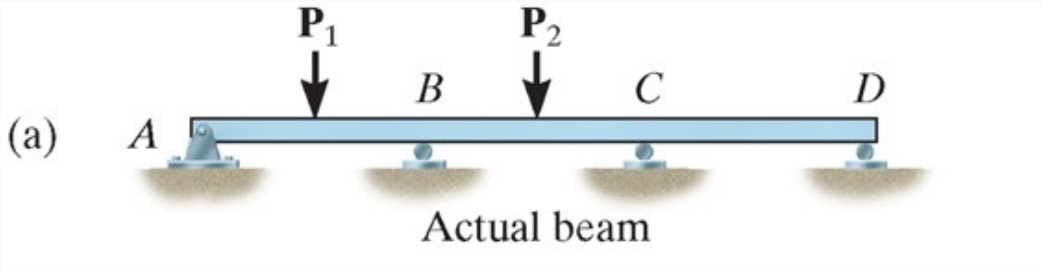
- To use superposition for finding deflection of statically indeterminate beams, we must first identify redundant reactions
- We initially remove these, then superpose them back such that the deflection at that point is 0
- The choice of which reaction(s) is redundant is arbitrary, we can choose whatever we are most comfortable with
- We use Appendix C to find deflection and slope

superposition



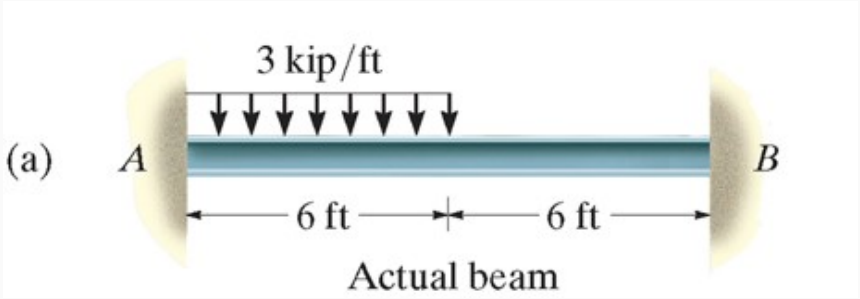
We can consider any reaction to be redundant.

higher order indeterminacy



We need to treat each reaction separately to match Appendix C.

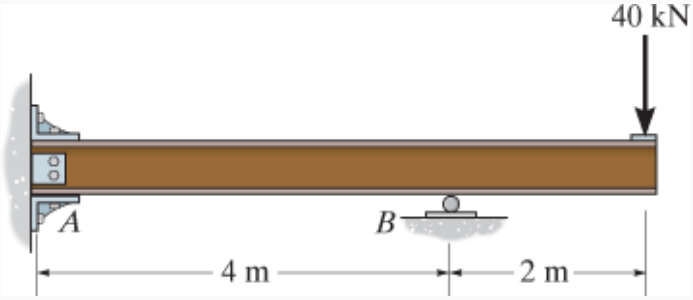
example 12.22



Determine the moment at B.

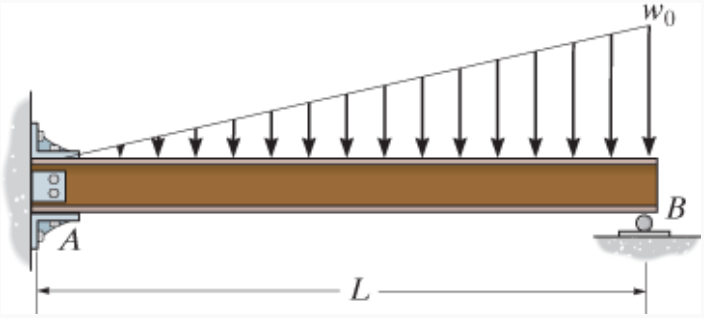
group problems

group one



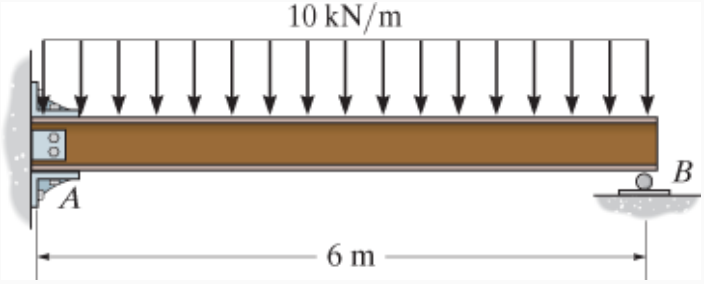
Determine the reactions at A and B (EI is constant).

group two



Determine the reactions at A and B (EI is constant).

group three



Determine the reactions at A and B. The support at B settles 2 mm. $E = 200$ GPa, $I = 65.0$(10-6)m 4.
