Name:

Homework 6
Due 15 October 2021

1. Find the shear stress at points A and B when $V = 450\,\text{kN}$. Draw the state of stress on a volume element at each point.

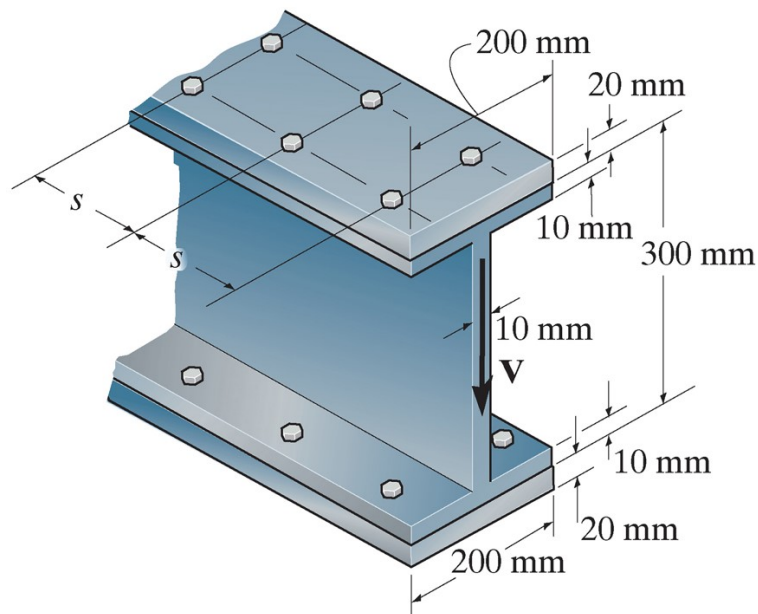

2. Find the maximum shear stress acting on the beam shown.

3. The overhanging beam is subjected to a uniform load of $w = 75\,\text{kN/m}$. Find the maximum shear stress in the beam.

4. Two identical $20\,\text{mm}$ plates are bolted to the top and bottom of a flange to form a built-up beam. For a shear force of $V = 400\,\text{kN}$ find the maximum bolt spacing, s, if each bolt has a shear strength of $45\,\text{kN}$

5. The beam shown is made by gluing two $1/2$ in c-channel strips together as sown. If the glue has a maximum shear stress of $\tau = 600$ psi find the maximum intensity, w_0, of the triangular distributed loading.
